2D and van der Waals materials exhibit radically new electrical and optical properties and are opening new research directions in the field

of nanophotonics. Polaritons in these materials can be used to confine light to the nanoscale, while via gate-tunability it is possible to create reconfigurable optical devices.

Optics of 2D and van der Waals materials ¦ Capasso Group
Abstract Designer heterostructures can now be assembled layer-by-layer with unmatched precision thanks to the recently developed deterministic placement methods to transfer two-dimensional (2D) materials. This possibility constitutes the birth of a very active research field on the so-called van der Waals heterostructures.

Although the 2D materials are interesting in their own right, an even larger potential lies in the possibility of reassembling different 2D crystals into new layered compounds . Such designer materials have been coined van der Waals heterostructures (vdWHs) with reference to the weak van der Waals forces holding the 2D crystal planes together.

The 2D materials are layered material with the thickness of one or more monolayers [66, 67] while atoms in the layer are covalently bonded and the layers are held together by van der Waals (vdW) forces [68]. Dimensional differences produce novel properties different from those of 3D materials.

Quasi van der Waals epitaxy nitride materials and devices ...
In commonly used 2D materials, researchers rely on the interaction between the thin layers, known as van der Waals interlayer coupling, to create charge transfer that is then used in devices. However, this interlayer coupling is limited because the charges are traditionally distributed evenly on the two sides of each layer.
